# Precipitation & Extreme Events Dashboard Review

- **By Yashaswi**

## Overview

The precipitation dashboard provides a strong representation of **precipitation patterns, variability, and extreme events**, emphasizing how precipitation behaves rather than just how much is observed.

## Strengths

- Clear focus on **variability (57.7%)**, which is critical for climate analysis
- Strong emphasis on **extreme events (~59.5K)** and their increase over time
- Effective identification of:
    - Increasing precipitation trends
    - Significant rise in extreme events after 2010
- Honest representation of **weak correlation (~0.13)** between temperature and precipitation
- Good use of visuals to communicate **regional differences**

## Feedback

- The dashboard identifies complexity and weak relationships but does not fully extend into **interpretation of what that means for understanding precipitation behavior**
- Extreme events are clearly highlighted but remain at an aggregated level, limiting deeper understanding of how these events evolve over time
- The insight correctly shows that relationships are inconsistent, but the implication of this finding is not clearly developed
- The overall narrative presents multiple insights (trend, variability, weak correlation) but lacks a fully connected explanation tying them into a single interpretation
- The weak correlation insight was well explained during the presentation, but this explanation is not reflected within the dashboard, reducing standalone interpretability

## Summary

The precipitation dashboard effectively captures variability and the rising importance of extreme events, but remains largely observational, with limited extension into interpretation, event behavior, and cohesive narrative development.
